The NetFPGA project is an effort to develop open-source hardware and software for rapid prototyping of computer network devices. The project targeted academic researchers, industry users, and students. It was not the first platform of its kind in the networking community. NetFPGA used an FPGA-based approach to prototyping networking devices. This allows users to develop designs that are able to process packets at line-rate, a capability generally unafforded by software based approaches. NetFPGA

The NetFPGA is the low-cost reconfigurable hardware platform optimized for high-speed networking. The NetFPGA includes the all fo the logic resources, memory, and Gigabit Ethernet interfaces necessary to build a complete switch, router, and/or security device. Because the entire datapath is implemented in hardware, the system can support back-to-back packets at full Gigabit line rates and has a processing latency measured in only a few clock cycles.

In engineering, hardware architecture refers to the identification of a system's physical components and their interrelationships. This description, often called a hardware design model, allows hardware designers to understand how their components fit into a system architecture and provides to software component designers important information needed for software development and integration.

The hardware architecture is a view of the physical architecture, which represents the hardware components and their interrelationships. The ESS Hardware block definition diagram is shown in Figure 17.42, and includes the Site Hardware and CMS Hardware block. These blocks aggregate the hardware components in a similar way as shown in Figure 17.39 for the ESS Software.
